Abstract

| 1 | In this project we develop, and study different statistical machine learning models |
|---|---|
| 2 | for predicting whether the number of available bikes at a given hour should be |
| 3 | increased, a project by the District Department of Transportation in Washington |
| 4 | D.C. The training data set consists of 1600 instances of hourly bike rentals, and |
| 5 | a test set of 400 instances. The models for prediction we have used are: Logistic |
| 6 | regression, Discriminant methods: LDA, QDA, k-Nearest Neighbour, and Tree |
| 7 | Based Methods. We have found that THE MODEL gives best prediction, with |
| 3 | accuracy ?????? |

13

14

16

18

20

21

29

30

31 32

10 1.1 From Intro

- (i) Explotre and preprocess data
- 12 (ii) try some or all classification methods, which are these?
 - Logistic Regression
 - Discriminant analysis: LDA, QDA
- K-nearest neighbor
 - Tree-based methods: classification trees, random forests, bagging
- Boositing
- (iii) Which of these are to be "put in producion"?

19 1.2 From Data analysis task

- Can any trend be seen comparing different hours, weeks, months?
 - Is there any diffrence between weekdays and holidays?
- Is there any trend depending on the weather?

23 **1.3 From Implementation of methods**

- Each group member should implement one family each, who did what shall be clear!
- 25 DNNs are encouraged to be implemented, do this if there is time. (DNN is not a thing a group
- 26 member can claim as their family.)
- 27 Implement a naive version, let's do: Always low_bike_demand

28 1.3.1 What to do with each method

- 1. Implement the method (each person individually)
- 2. Tune hyper-parameters, discuss how this is done (each person individually)
- 3. Evaluate with for example cross-validation. Don't use E_{k-fold} (what is that?) (need to do together)
- 4. (optional) Think about input features, are all relevant? (together)
- Before training, unify pre-processing FOR ALL METHODS and choose ONE OR MULTIPLE metrics to evaluate the model. (is it neccesary to have the same for all?, is it beneficial?) Examples:
- accuracy
- f1-score
- se recall
- precision
- Use same test-train split for ALL MODELS

41 2 Introduction

- 42 Statistical machine learning is a subject that aims to build and train algorithms, that analyse large
- amount of data, and make predictions for the future, which are computed by using established
- 44 statistical models, and tools from functional analysis. This is a project in supervised, statistical
- 45 machine learning, where several models were created, and trained, in order to analyse which one of
- 46 them gives best prediction for the project "Do we need more bikes", where we want to understand,
- 47 and predict if there is a high, or low demand of city bikes in the public transportation of Washington,
- a project by the District Department of Transportation in Washington D.C..
- 49 The data set used for training our models, consist of 15 variables, containing quantitative/qualitative
- 50 data. We developed several models, and evaluated them with cross-validation, in order to understand
- which algorithm gives the best prediction.

2 3 Theoretical Background

53 3.1 Mathematical Overview of the Models

54 3.1.1 Logistic Regression

55 The backbone of logistic regression is linear regression, i.e. finding the least-squares solution to an

56 equation system

$$X\theta = y \tag{1}$$

57 given by the normal equations

$$X^T X \theta = X^T y \tag{2}$$

where X is the training data matrix, θ is the coefficient vector and b is the training output. The

parameter vector is then used in the sigmoid function:

$$\sigma(z) = \frac{e^z}{1 + e^z} : \mathbb{R} \to [0, 1], \tag{3}$$

$$z = x^T \theta, \tag{4}$$

where x is the testing input. This gives a statistical interpretation of the input vector. In the case of a binary True/False classification, the value of the sigmoid function then determines the class.

62 3.1.2 Random forest

63 The random forest method is a based upon decision trees, i.e. dividing the data point into binary

64 groups based on Gini-impurity, entropy or classification error, Gini being the most common. These

65 divisions are then used to create a binary tree shown in figure ??Tree) and where thee leaf-nodes are

used to classify the target variables bases on the input. As of itself the dicition tree tends to have

unsatisfying results which leads to methodes like random forest that boost its accuracy.

3.1.3 Non-parametric method: k-Nearest Neighbour

69 k-Nearest Neighbour(k-NN) is a distance based method that takes a k amount of points from the

training data set, called *neighbours*, computes the distance between them, then assumes that the

predicted value $\hat{y}(x_*)$ follows the trend of the k- nearest neighbours. Since k-NN uses the training

data explicitly it is also called a *nonparametric* method.

73 The k-NN method can be divided into several subcategories, inter alias classification k-NN method,

74 regression k-NN method. In this project, we are using the classification method, since we are trying

75 to predict in which of the two classes low, or high demand, the given, and predicted data points

76 belong.

68

77 The classification k-NN algorithm evaluates $\hat{y}(x_*)$ by computing the most frequently occurring class

among the k nearest neighbours. Here, we try to identify whether a data point belong to the high

demand-class. Denote c = high demand class. For simplicity, assume Euclidean ambiance. Then

$$\hat{y}(x_*) = \arg\max_{c} \sum_{n \in \mathbb{N}} \chi_{(y_i = c)},$$

where y_i is the class of the nearest neighbour, χ is the characteristic function

$$\chi_{(y_i=c)} = \begin{cases} 1 & \text{if } y_n = c, \\ 0 & \text{otherwise.} \end{cases}$$

81 It is very common to use a weighted sum to predict the next value, i.e.

$$\hat{y}(x_*) = \arg\max_{c} \sum_{n \in \mathbb{N}} \frac{\chi_{(y_n = c)}}{d(x, x_n)},$$

where d is the standard Euclidean metric, computing the distance between an input x, and a neighbour

83 x_n

84 When using this model it is important to choose an optimal k-value. There are several tests for this,

being here we implement uniform weighting, and distance weighting. The first algorithm creates a k-NN

model for each new $k \in [1,500]$, and trains the model with uniform weights, i.e. the contribution of 86 all neighbours is equal. Similarly, the latter trains a k-NN classifier for each $k \in [1, 500]$, with the 87 difference that it uses distance based weighting, i.e. closer neighbours have greater influence. After 88 testing different upper boundaries for k, the two models gave good results in the interval [1,500], see 89 Figure 1. From the figures, we can see that the second test gives a better value for k, since the plot 90 follows smoother trend, in comparison to the uniform weighting test, which makes it easier to identify 91 an optimal k value (k = 120). Moreover, the distance weighting algorithm is providing results for larger values of k, that is for $k \in [1, 400)$ before the curve converges, while the uniform weighting 93 algorithm converges earlier, when k = 120. This means that for large k, both test algorithms make 94 prediction based on the most common class in the data set, instead of making prediction based on the 95 behaviour of the neighbours. Thus for sufficiently large k, for any given data point, the model will 96 consider unnecessarily large amount of neighbours, and the prediction will be evaluated to belong to 97 the most frequent class. Since the distance weighting has a larger range of k-value, it should be more 98 trustworthy. 99

When k = 120, the accuracy of the model is 92%.

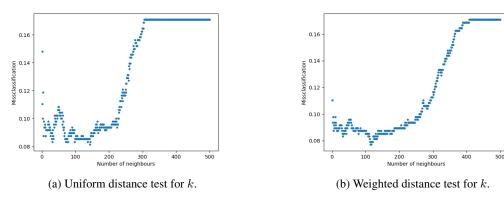

Figure 1: Test for choosing an optimal k-value.

3.1.4 Discriminant analysis: LDA and QDA

Linear Discriminant Analysis is a generative model, which means it is a model that's creating and using a probability distribution $P(\mathbf{x}, y)$ to create an estimation for the probability $P(y = m|\mathbf{x})$ using bayes theorem.

105 Bayes theorem is:

101

$$p(y|\mathbf{x}) = \frac{p(y,\mathbf{x})}{p(\mathbf{x})} = \frac{p(y)p(\mathbf{x}|y)}{\int_{\mathcal{Y}} p(y,\mathbf{x})}$$

For the discrete version it is obtained:

$$p(y = m|\mathbf{x}) = \frac{p(y = m)p(\mathbf{x}|y = m)}{\sum_{m=1}^{M} p(y = m)p(\mathbf{x}|y = m)}$$

For this form of the equation to be useful, it is necessary to obtain an accurate estimation of p(y=m) and $p(\mathbf{x}|y=m)$ for all classes m.

In LDA, p(y=m) is estimated by counting the percentage of data points (in the training data) being in each of the classes and using that percentage as the probability of a data point being in that class. In mathematical terms:

$$p(y = m) = \frac{1}{n} \sum_{i=1}^{n} \mathbb{I}\{y_i = m\} = \frac{n_m}{n}$$

To estimete the probability distribution $p(\mathbf{x}|y=m)$, a multi-dimensional gaussian distribution is used:

$$\mathcal{N}(\mathbf{x}|\mu, \mathbf{\Sigma}) = \frac{1}{(2\pi)^{d/2} |\mathbf{\Sigma}|^{1/2}} exp\left(-\frac{1}{2}(\mathbf{x} - \mu)^T \mathbf{\Sigma}^{-1}(\mathbf{x} - \mu)\right)$$

Where x is the d-dimentional data point, μ is the (d-dimentional) mean of the random variable. Σ is the symetric, positive definite covariance matrix defined by:

$$\Sigma = \frac{1}{n-M} \sum_{m=1}^{M} \sum_{i: y_i = m} (\mathbf{x}_i - \mu_m) (\mathbf{x}_i - \mu_m)^T$$

Using these estimations results in an expression for the quantity $p(y = m|\mathbf{x}) \forall m$. LDA then uses 116 maximum likelyhood to categorize an input x into a class m. 117

142

143

144

145

Quadratic discriminant analysis (QDA) is heavily based of LDA with the sole difference being how the covariance matrix Σ is created. In LDA, the covariance matrix is assumed to be the 120 same for data in each and every class. In QDA however, the covariance matrix is calculated for each class as follows:

$$\Sigma_m = \frac{1}{n_m - 1} \sum_{i:y_i = m} (\mathbf{x}_i - \mu_m) (\mathbf{x}_i - \mu_m)^T$$

One thing to note about LDA and QDA is that the use of a multi-variable gaussian distribution 123 benefints normally distributed variables. In this project however, there is a dependance on positive 124 definite values which are not normally distributed by nature. This is an issue when using QDA since 125 in the class of high_bike_demand, all data points have a snow depth of 0 and has hence no variance. 126 This results in this class having a undefined inverse for the covariance matrix. The solution used was 127 to exclude this variable from this model. 128

129 3.2 Input Data Modification

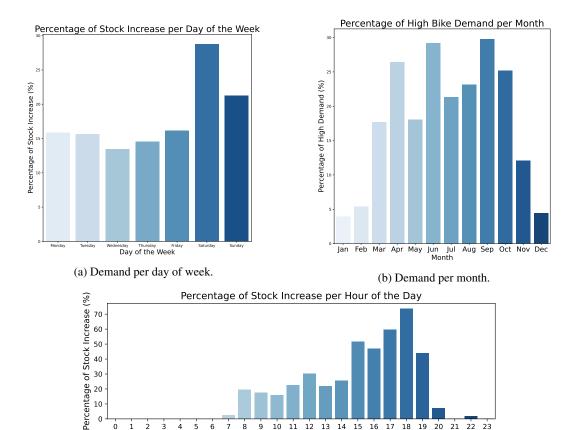

By plotting the data and analyzing the .csv file, some observations were made. The different inputs 130 were then changed accordingly: 131

- Kept as-is: weekday, windspeed, visibility, temp
- Modified:
 - month split into two inputs, one cosine and one sine part. This make the new inputs linear and can follow the fluctuations of the year. The original input was discarded.
 - hour_of_day split into three boolean variables: demand_day, demand_evening, and demand_night, reflecting if the time was between 08-14, 15-19 or 20-07 respectively. This was done because plotting the data showed three different plateaues of demand for the different time intervals. The original input was discarded.
 - snowdepth, precip were transformed into booleans, reflecting if it was raining or if there was snow on the ground or not. This was done as there was no times where demand was high when it was raining or when there was snow on the ground.
- Removed: cloudcover, day_of_week, snow, dew, holiday, summertime. These were removed due to being redundant (e.g. summertime), not showing a clear trend (e.g. cloudcover), giving a worse score when used, or all three (e.g. day_of_week).

46 4 Data Analysis

In the given data, there are some numerical and categorical features:

- *Numerical*: temp, dew, humidity, precip, snow, snowdepth, windspeed, cloudcover and visibility.
- Categorical: hour_of_day, day_of_week, month, holiday, weekday, summertime, and increase_stock

(c) Demand per hour of day.

Figure 2: Bike demand vs. day of week and month.

10 11 12 13 Hour of the Day

There are some trends seen in the data when it comes to time and weather. From figure 2, one can see a periodic relationship for the months, where there is a higher demand during the warmer months, loosely following a trigonometric curve. Over the week, the demand is rather stable, with a peak on the weekend, especially saturdays.

Looking at the weather (figure 3); if there is rain or if there is snow on the ground, there is close to always low demand. Cloudcover did not make a big impact, which is also intuitive, as a cloudy day does not make biking more difficult. Dew point also does not have a clear trend, while humidity however has a clear trend downwards as the humidity increases. Temperature had a more clear impact, where more people wanted to bike the warmer it got.

The overall trend is that about one eigth of observations correspond to a high bike demand. During the night, or in bad weather, the demand is (intuitively) low. But during rush hour (figure 2c), the demand is very high, and should probably be increased in order to minimize excessive CO₂ emissions.

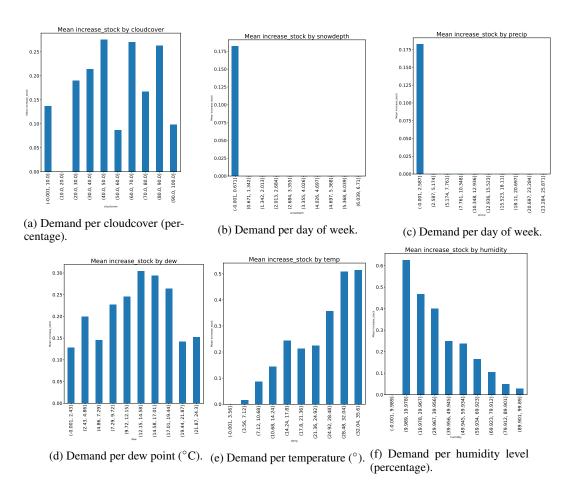

Figure 3: Bike demand vs. various weather parameters.

164 5 Result

The method used to evaluate the different models where simply chosen to be the accuracy defined by:

$$accuracy = \frac{n_{correct}}{n_{tot}}$$

166 The different models were tested and the accuracy where:

Accuracy of the models

| Model | Accuracy |
|-------|----------|
| LDA | 86% |
| QDA | 86% |
